CS161 Computer Security

Weaver and Popa

T

## (and How To Break It) Nicholas C Weaver

### Tor: The Onion Router Anonymous Websurfing

- Tor actually encompasses many different components
- The Tor network:

CS 161 Computer Security

- Provides a means for anonymous Internet connections with low(ish) latency by relaying connections through multiple Onion Router systems
- The Tor Browser bundle:
  - A copy of FireFox extended release with privacy optimizations, configured to only use the Tor network
- Tor Hidden Services:
  - Services only reachable though the Tor network
- Tor bridges with pluggable transports:
  - Systems to reach the Tor network using encapsulation to evade censorship

### The Tor Threat Model:

### Anonymity of content against local adversaries

- CS 161 Computer Security
  - The goal is to enable users to connect to other systems "anonymously" but with low latency
    - The remote system should have no way of knowing the IP address originating traffic
    - The local network should have no way of knowing the remote IP address the local user is contacting
  - Important what is excluded: The *global* adversary
    - Tor does not even attempt to counter someone who can see *all* network traffic

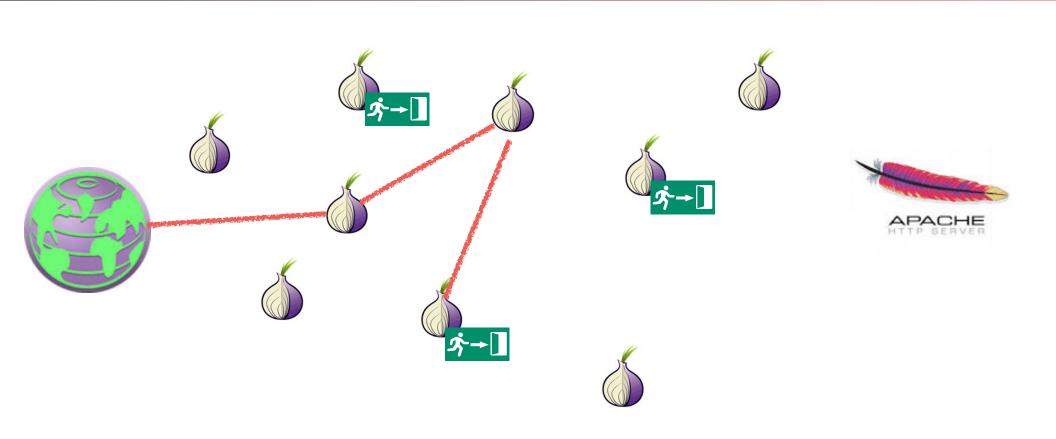

### The High Level Approach: Onion Routing

#### CS 161 Computer Security

- The Tor network consists of thousands of independent Tor nodes, or "Onion Routers"
  - Each node has a distinct public key and communicates with other nodes over TLS connections
- A Tor circuit encrypts the data in a series of layers
  - Each hop away from the client removes a layer of encryption
  - Each hop towards the client adds a layer of encryption
- During circuit establishment, the client establishes a session key with the first hop...
  - And then with the second hop through the first hop

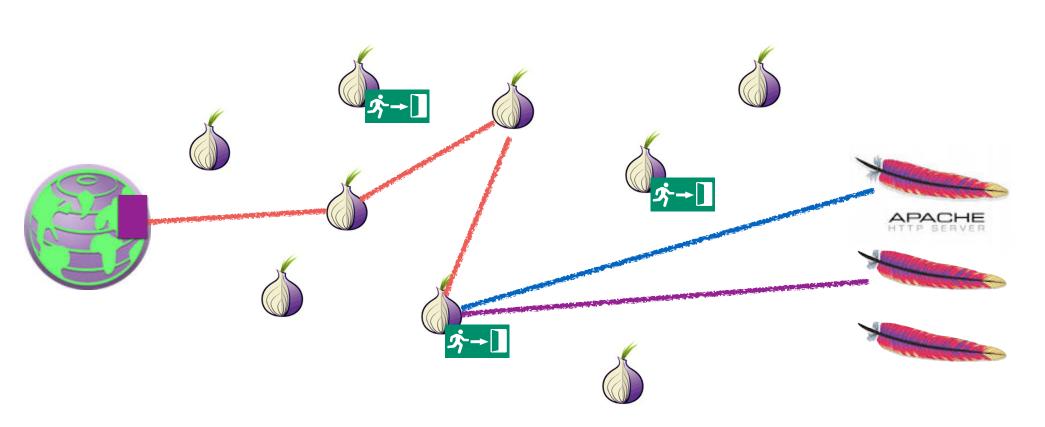

### Tor Routing In Action

CS 161 Computer Security

### Tor Routing In Action

CS 161 Computer Security

#### Creating the Circuit Layers...

#### CS 161 Computer Security

- The client starts out by using an authenticated DHE key exchange with the first node...
  - Creating a session key to talk to OR1
    - This first hop is commonly referred to as the "guard node"
- It then tells OR1 to extend this circuit to OR2
  - Creating a session key for the client to talk to OR2 that OR1 does not know
  - And OR2 doesn't know what the client is, just that it is somebody talking to OR1 requesting to extend the connection...
- It then tells OR2 to extend to OR3...
  - And OR1 won't know where the client is extending the circuit to, only OR2 will

### Unwrapping the Onion

#### CS 161 Computer Security

- Now the client sends some data...
  - E(K<sub>or1</sub>,E(K<sub>or2</sub>,E(K<sub>or3</sub>, Data)))
- OR1 decrypts it and passes on to OR2
  - E(K<sub>or2</sub>, E(K<sub>or3</sub>, Data))
- OR2 then passes it on...
- Generally go through at least 3 hops...
  - Why 3? So that OR1 can't call up OR2 and link everything trivially

Weaver and Por

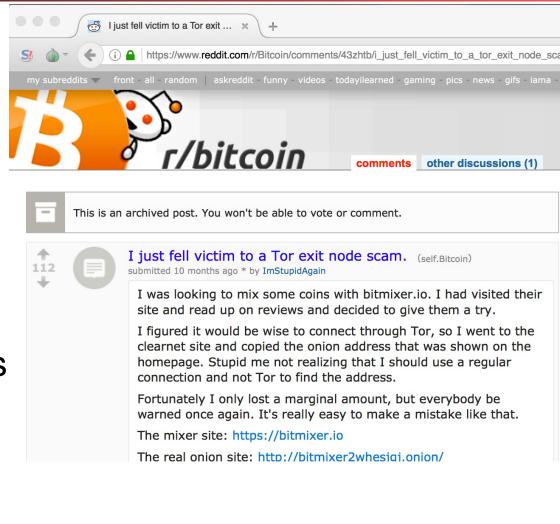

#### The Tor Browser...

#### CS 161 Computer Security

- Surfing "anonymously" doesn't simply depend on hiding your connection...
- But also configuring the browser to make sure it resists tracking
  - No persistent cookies or other data stores
  - No deviations from other people running the same browser
- Anonymity only works in a crowd...
  - So it really tries to make it all the same
- But by default it makes it easy to say "this person is using Tor"

### But You Are Relying On Honest Exit Nodes...

- CS 161 Computer Security
  - The exit node, where your traffic goes to the general Internet, is a man-in-themiddle...
    - Who can see and modify all nonencrypted traffic
    - The exit node also does the DNS lookups
  - Exit nodes have not always been honest...

### Anonymity Invites Abuse... (Stolen from Penny Arcade)

CS 161 Computer Security

Ш

## This Makes Using Tor Browser Painful...

### And Also Makes Running Exit Nodes Painful...

CS 161 Computer Security

- If you want to receive abuse complaints...
  - Run a Tor Exit Node
- Assuming your ISP even allows it...
  - Since they don't like complaints either
- Serves as a large limit on Tor in practice:
  - Internal bandwidth is plentiful, but exit node bandwidth is restricted

### One Example of Abuse: The Harvard Bomb Threat...

#### CS 161 Computer Security

- On December 16th, 2013, a Harvard student didn't want to take his final in "Politics of American Education"...
  - So he emailed a bomb threat using Guerrilla Mail
  - But he was "smart" and used Tor and Tor Browser to access Guerrilla Mail
- Proved easy to track
  - "Hmm, this bomb threat was sent through Tor..."
  - "So who was using Tor on the Harvard campus..." (look in Netflow logs..)
  - "So who is this person..." (look in authentication logs)
  - "Hey FBI agent, wanna go knock on this guy's door?!"
- There is no magic Operational Security (OPSEC) sauce...
  - And again, anonymity only works if there is a crowd

### Censorship Resistance: Pluggable Transports

CS 161 Computer Security

- Tor is really used by two separate communities
  - Anonymity types who want anonymity in their communication
  - Censorship-resistant types who want to communicate despite government action
- Vanilla Tor fails the latter completely
- So there is a framework to deploy bridges that encapsulate Tor over some other protocol
  - So if you are in a hostile network...

### OBS3 Blocking: China Style

#### CS 161 Computer Security

- Its pretty easy to recognize something is *probably* the Tor obs3 obfuscation protocol
  - But there may be false positives...
    - And if you are scanning all internet traffic in China the base rate problem is going to get you
- So they scan all Internet traffic looking for obs3...
  - And then try to connect to any server that looks like obs3
- If it is verified as an obs3 proxy...
  - China then blocks that IP/port for 24 hours

### Meek: Collateral Freedom

#### CS 161 Computer Security

- Meek is another pluggable transport
  - It uses Google App engine and other cloud services
- Does a TLS connection to the cloud service
- And then encapsulates the Tor frames in requests laundered through the cloud service
- Goal is "Too important to block"
  - The TLS handshake is to a legitimate, should not be blocked service
  - And traffic analysis to tell the difference between Meek and the TLS service is going to be hard/have false positives

#### Tor Browser is also used to access Tor Hidden Services aka .onion sites

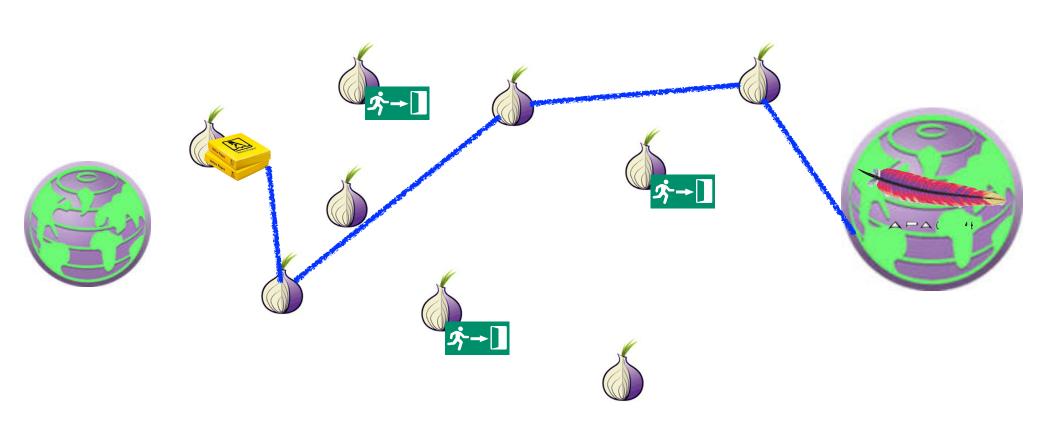

- Services that only exist in the Tor network
  - So the service, not just the client, has possible anonymity protection
  - The "Dark Web"

CS 161 Computer Securit

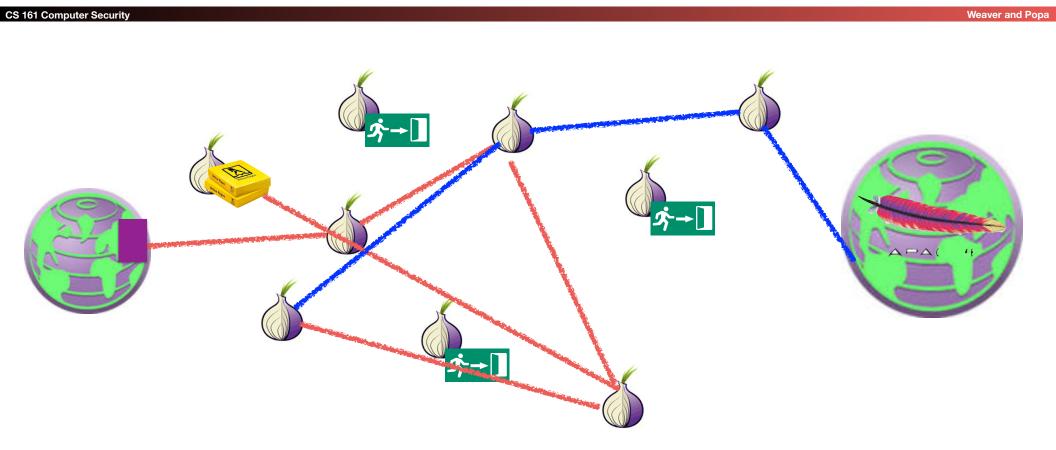

- A hash of the hidden service's public key
  - http://pwoah7foa6au2pul.onion
    - AlphaBay, one of many dark markets
  - https://facebookcorewwwi.onion
    - In this case, Facebook spent a lot of CPU time to create something distinctive
- Using this key hash, can query to set up a circuit to create a hidden service at a rendezvous point

### Tor Hidden Service: Setting Up Introduction Point

CS 161 Computer Security

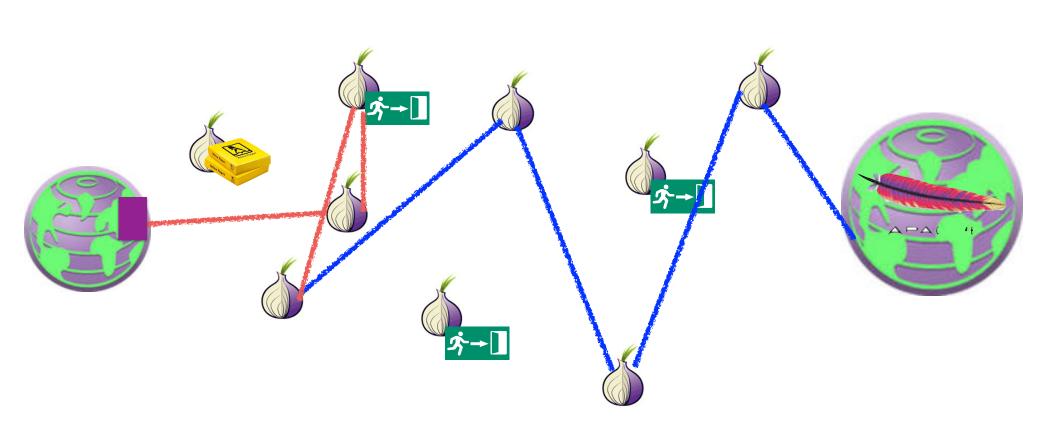

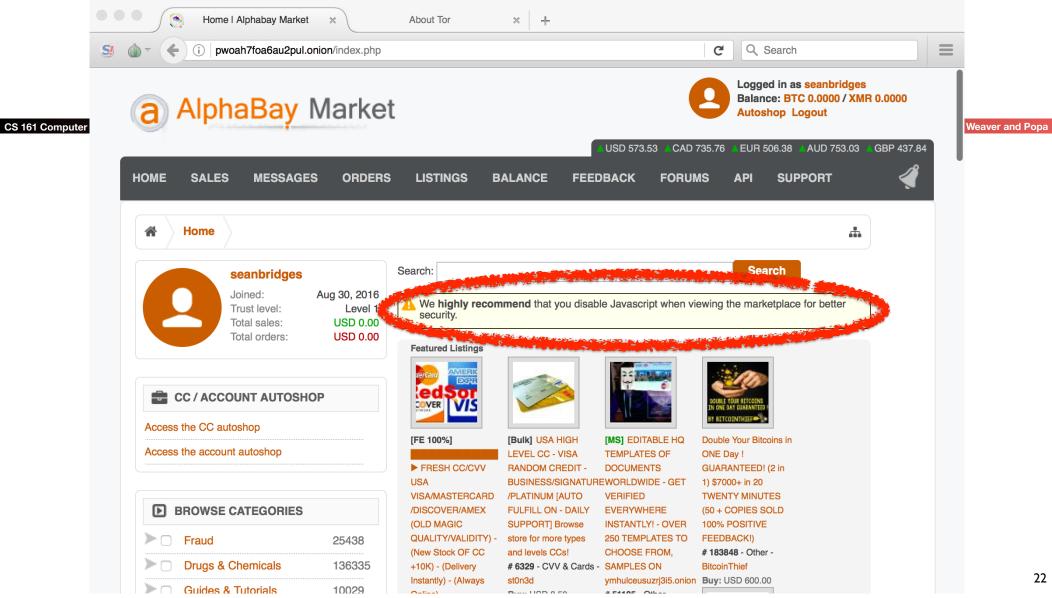

### Tor Hidden Service: Query for Introduction, Arrange Rendevous

#### Tor Hidden Service: Rendevous and Data

CS 161 Computer Security

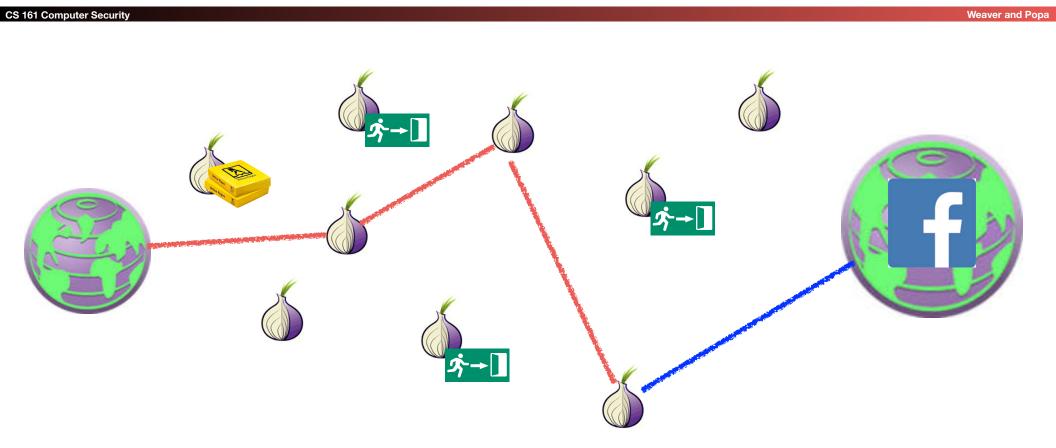

#### Remarks...

#### CS 161 Computer Security

- Want to keep your guard node constant for a long period of time...
  - Since the creation of new circuits is far easier to notice than any other activity
- Want to use a different node for the rendezvous point and introduction
  - Don't want the rendezvous point to know who you are connecting to
- These are *slow!*
  - Going through 6+ hops in the Tor network!

#### Non-Hidden Tor Hidden Service: Connect Directly to Rendezvous

### Non-Hidden Hidden Services Improve Performance

#### CS 161 Computer Security

- No longer rely on exit nodes being honest
  - No longer rely on exit node bandwidth either
- Reduces the number of hops to be the same as a not hidden service
- Result: Huge performance win!
  - Not slow like a hidden service
  - Not limited by exit node bandwidth

# Real use for *true hidden* hidden services

#### CS 161 Computer Security

- "Non-arbitrageable criminal activity"
  - Some crime which is universally attacked and targeted
    - So can't use "bulletproof hosting", CDNs like CloudFlare, or suitable "foreign" machine rooms
- Dark Markets
  - Marketplaces based on Bitcoin or other alternate currency
- Cybercrime Forums
  - Hoping to protect users/administrators from the fate of earlier markets
- Child Exploitation

### The Dark Market Concept

- Four innovations:
- A censorship-resistant payment (Bitcoin)
  - Needed because illegal goods are not supported by Paypal etc
    - Bitcoin/cryptocurrency is the only game in town for US/Western Europe after the Feds smacked down Liberty Reserve and eGold
- An eBay-style ratings system with mandatory feedback
  - Vendors gain positive reputation through continued transactions
- An escrow service to handle disputes
  - Result is the user (should) only need to trust the market, not the vendors
- Accessable *only* as a Tor hidden service
  - Hiding the market from law enforcement

### The Dark Markets: History

- All pretty much follow the template of the original "Silk Road"
  - Founded in 2011, Ross Ulbricht busted in October 2013
- The original Silk Road actually (mostly) lived up to its libertarian ideals
  - Including the libertarian ideal that if someone rips you off you should be able to call up the Hell's Angels and put a hit on them
    - And the libertarian idea if someone is foolish enough to THINK you are a member of the Hell's Angels you can rip them off for a large fortune for a fake hit
- Since then, markets come and go
  - But you can generally find the latest gossip on "deepdotweb" and Reddit /r/darknetmarkets

### The Dark Markets: Not So Big, and **Not Growing!**

- Weaver and Popa
- Kyle Soska and Nicolas Christin of CMU have crawled the dark markets for years
  - These markets *deliberately* leak sales rate information from mandatory reviews
- So simply crawl the markets, see the prices, see the volume, voila...
- Takeaways:
  - Market size has been relatively steady for years, about \$300-500k a day sales
  - Dominated by Pot, MDMA, and stimulants, with secondary significance with opioids and psychedelics
  - A few sellers and a few markets dominate the revenue: A fair bit of "Winner take all"
    - But knock down any "winner" and another one takes its place

#### The Scams...

- You need a reputation for honesty to be a good crook
  - But you can burn that reputation for short-term profit
- The "Exit Scam" (e.g. pioneered by Tony76 on Silk Road)
  - Built up a positive reputation
  - Then have a big 4/20 sale
  - Require buyers to "Finalize Early"
    - Bypass escrow because of "problems"
  - Take the money and run!
- Can also do this on an entire *market* basis
  - The "Sheep Marketplace" being the most famous

### And then the Child Exploitation types

- This is why I'm quite happy to see Tor Hidden Services burn!!!
  - Because these do represent a serious problem: The success against "PlayPen" shows just how major these are
- A far bigger systemic problem than the dark markets:
  - Dark markets are low volume, and not getting worse
    - Plus the libertarian attitude of "drug users are mostly harming themselves, its the drugassociated crime that is the problem"
      - No indication of any *successful* murder resulting from dark market activity
  - But these are harming others
  - They are also harming Tor: Tor itself is a very valuable tool for many legitimate uses, but the presence of the child exploitation sites on hidden services is a stain on Tor itself

### Deanonymizing Hidden Services: Hacking...

#### CS 161 Computer Security

- Most dark-net services are not very well run...
  - Either common off-the-shelf drek or custom drek
- And most have now learned don't ask questions on StackOverflow
  - Here's looking at you, frosty...
- So they don't have a great deal of IT support services
  - A few hardening guides but nothing really robust
- Child exploitation is probably worse that dark markets
  - Dark markets at least attract some libertarian-types who will provide external aid

#### Onionscan...

#### CS 161 Computer Security

- A tool written by Sarah Jamie Lewis
  - Available at https://github.com/s-rah/onionscan
- Idea is to look for very common weaknesses in Tor Hidden services
  - Default apache information screens
  - Web fingerprints
  - I believe a future version will check for common ssh keys elsewhere on the Internet
- Its really "dual use"
  - .onion site operators should use to make sure they aren't making rookie mistakes
  - Those investigation .onion sites should use to see if the target site made a rookie mistake!

### Deanonymizing Visitors To Your Site FBI Style

#### CS 161 Computer Security

- Start with a Tor Browser Bundle vulnerability...
  - Requires paying for a decent vulnerability: Firefox lacks sandboxing-type protections but you have to limit yourself to JavaScript
- Then take over the site you want to deanonymize visitors to...
- And simply hack the visitors to the site!
  - With a limited bit of malcode that just sends a "this is me" record back to an FBI-controlled computer

### A History of NITs

- The FBI calls their malicious code a NIT or Network Investigatory Technique
  - Because it sounds better to a magistrate judge than saying "we're gonna go hacking"
- The exploit attempts to take over the visitor's browser
- But the payload is small: just a "I'm this computer" sent over the Internet to an FBI controlled Internet address

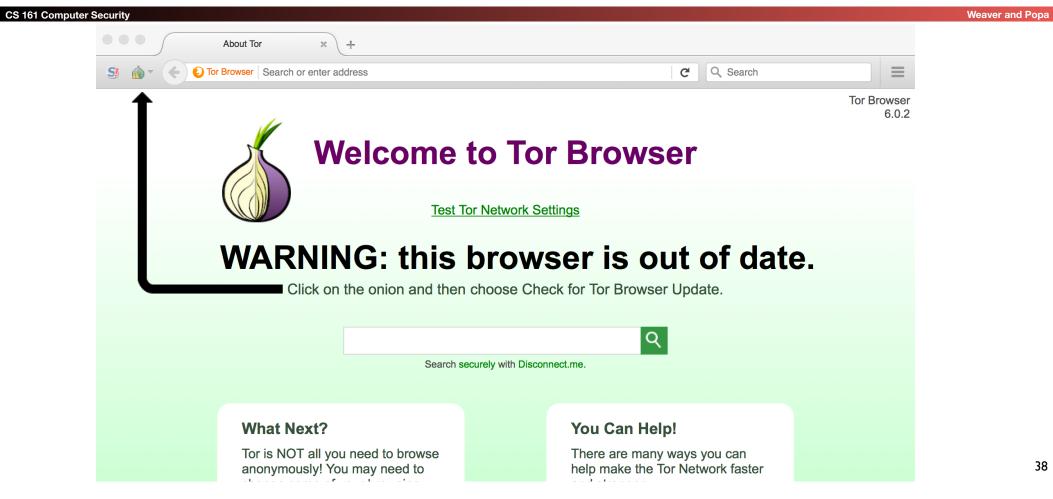

### A History of NITs: PedoBook

#### CS 161 Computer Security

- The first known NIT targeting a hidden service was "PedoBook" back in 2012
  - Back then, many people used other web browsers to interact with Tor hidden services
- The NIT actually didn't even qualify as malcode
  - And a *defense* expert actually argued that it isn't hacking and probably didn't actually need a warrant
- Instead it was the "Metasploit Decloaking" flash applet:
  - A small bit of Flash which contacts the server directly, revealing the visitor's IP address

### A History of NITs: Freedom Hosting

- The second big NIT targeted FreedomHosting
  - A hosting provider for Tor Hidden services with an, umm, generous policy towards abuse
    - Hosted services included TorMail (a mail service through Tor) and child porn sites
- FBI replaced the entire service with a NIT-serving page
- Fallout:
  - Very quickly noticed because there are multiple legit users of TorMail
  - Targeted an older Firefox vulnerability in Tor Browser
- Tor browser switched to much more aggressive autoupdates: Now you *must* have a zero-day for a NIT payload to work

### A History of NITs: Playpen

#### CS 161 Computer Security

- The big one: PlayPen was a hidden service for child pornographers
  - In February 2015, the FBI captured the server and got a warrant to deploy a NIT to logged in visitors
    - The NIT warrant is public, but the malcode itself is still secret
- What we do know:
  - This was big: hundreds of arrests, many abuse victims rescued
  - It almost certainly used a zero-day exploit for Tor Browser
- Courts are still hashing this out over two big questions
  - Is it valid under Rule 41?
    - Most have conclude "no, but a technical not constitutional flaw"
  - Does the defense have a right to examine the exploit?
    - I'll argue no, but some defense attorneys have successfully used a graymail technique

### A History of NITs: Yesterday's News!

- Weaver and Popa
- Someone (probably the French police) captured a child porn site called the "GiftBox"
  - They modified it to serve up a NIT
- The NIT payload was almost identical to the one in the Freedom Hosting case
  - Suggesting assistance from either the FBI or the FBI's contractor
- The exploit was a new zero-day exploit targeting Firefox
  - Patch released within hours
  - And yes, it was a C-related memory corruption (naturally)

### NITs won't work well in the future against Tor!

- The current Tor browser hardened branch is just that, *hardened* 
  - And it will become mainstream in a future version: it uses a technique, *selfrando*, with *no currently known workaround!*
- Hardening will require that breaking Tor browser, even to just send a "I'm here" message, will require a chain of exploits
  - An information leakage to determine the address of a function and enough content in that function to enable an attack
  - Or the leakage of a lot of functions
  - PLUS a conventional vulnerability
  - And just wait until the Firefox rendering engine gets sandboxed too...
  - And ad in darknet users who are running without JavaScript
- Upshot: the current FBI exploit will need a massive upgrade if it will work at all!
  - And future exploits will be *vastly* more expensive and rarer
  - We should thank the FBI for their very valuable contributions to software hardening

# If Adversary Can See Both In-and-Out All Bets Are Off...

#### CS 161 Computer Security

- Tor is specifically not designed to resist the "global passive adversary"
  - In fact, no *low latency* anonymity network can resist such an adversary without adding cover traffic
    - And if you ad cover traffic this vastly increases overhead and has to explicitly limit performance
- Not a major weakness for most uses...
  - Adversary needs to see both the entry node and the exit node
- But a *yuge* weakness for hidden services and visitors to compromised hidden services

### Step By Step: Deanonymizing Hidden Services (1)

Weaver and Po

- Slowly (Slowly!) spin up a large number of Tor nodes
  - They should not be exit nodes but just entry nodes/relays, and should use multiple hosting providers
  - After the CERT/CC debacle, the Tor project became very alert to many nodes joining at once
  - And you don't want to run a Tor exit node: You will get nastygrams if you run a Tor exit

### Step by Step: Deanonymizing Hidden Services (2)

CS 161 Computer Security

- Once you have about ~10% of the Tor network
  - In theory you could deanonymize about 1% of the Tor traffic if you included exit nodes...
    - Which is why the Tor community worries about this
    - But running exit nodes brings a lot of grief...
  - But you can deanonymize the hidden servers a lot more!
- Connect to a targeted hidden service through Tor
  - Now send data to and from that hidden service
  - Look for corresponding marked data flows in your relays
- If the hidden service connected to one of your relays... WIN!

### Flow Marking

- In connecting to the target service, you don't just send a request...
  - You break it up into pieces making it easier to "mark" the flow so you see it on the other side
- You also get lots of interesting timing information just from clicking around
  - Makes it easy to see your signal

### You win when...

#### CS 161 Computer Security

- Either the hidden service choses your node as a guard node
  - If you want to be destructive, you can speed this up by checking when you are a relay but not the guard, DOS the identified guard node to force the HS to create a new circuit
- Or you detect the service's "private" guard node
  - Some hidden service operators believe they should run their own guard node only
    - The original Silk Road did this
  - Which you now issue a pen-register order on and find the real server
